## Def. Topology

Let  $X$  be some set and  $\mathcal{T} \subseteq \mathcal{P}(X)$  be a collection

Then  $\mathcal{T}$  is a topology iff

1.  $X \in \mathcal{T}$
2.  $\forall A \subseteq \mathcal{T} : |A| < \infty \Rightarrow \bigcap_{a \in A} a \in \mathcal{T}$
3.  $\forall A \subseteq \mathcal{T} : \bigcup_{a \in A} a \in \mathcal{T}$

We call  $X$  a topological space iff it has a topology

For a topology  $\mathcal{T}$  we call  $A \in \mathcal{T}$  open

## Def. Closed

$Y \subseteq X$  is said to be closed iff  $Y^c := X \setminus Y$  is open

## lemma

Let  $X$  be a topological space then for any collection  $\{A_i\}_{i \in I}$  of closed sets we have

1. if  $|I| < \infty$  then  $\bigcup_{i \in I} A_i$  is closed
2.  $\bigcap_{i \in I} A_i$  is closed

### Proof of 1.

$$\left(\bigcup_{i \in I} A_i\right)^c = \left(\left(\bigcup_{i \in I} A_i\right)^c\right)^c = \left(\bigcap_{i \in I} A_{ci}\right)^c$$

Since each  $A_i$  is closed,  $A_{ci}$  is open and  $I$  is finite so the finite intersection is open as well, taking its complement gives a closed set.

### Proof of 2.

$$\left(\bigcap_{i \in I} A_i\right)^c = \left(\left(\bigcap_{i \in I} A_i\right)^c\right)^c = \left(\bigcup_{i \in I} A_{ci}\right)^c$$

again,  $A_i$  is closed so  $A_{ci}$  is open so the union of opens is open, thus its complement is closed

## Def. closure

Let  $A \subseteq X$  be a subset of a topological space  $X$ , then

the closure of  $A$  is given by  $\bar{A} := \bigcap_A$

By the preceeding lemma, the closure is obviously closed since its an intersection of closed sets

## Theorem 1, characterization of closed

Let  $A \subseteq X$  be a subset of a topological space  $X$ , then

$A$  is closed iff  $A = \bar{A}$

### Proof

We first prove the left right implication ( $\Rightarrow$ ) so suppose  $A$  is closed, then  $A$  is a closed set containing  $A$  so

$A \subseteq \bar{A}$ ,  $A$  is closed, by definition of the closure this implies  $\bar{A} \subseteq A$

But any of the sets forming the intersection contain  $A$  so we get

$$A = \bigcap_A A, \text{ therefore we have}$$

$$A \subseteq \bar{A} \subseteq A \text{ which gives us } A = \bar{A}$$

Now lets proceed with the right left implication ( $\Leftarrow$ )

Suppose we have  $A = \bar{A}$  then

$$A = \bigcap_A, \text{ by the preceeding lemma, an arbitrary intersection of closed sets is closed}$$

so we are immediately done.

## Def neighbourhood

Let  $x \in X$  be a point in some topological space  $X$  then the neighbourhood of  $x$  is given by

$$N(x) := \{U \in \mathcal{T} : x \in U\}$$

## Theorem 2, consistency with alternative definition

Let  $A$  be a subset of a topological space  $X$  then

$$A \text{ is closed iff } \forall U \in \mathcal{T} : A \cap U \subseteq X \setminus A$$

### Proof

( $\Rightarrow$ )

assume  $A$  is closed, then

$$A = \bigcap_{\alpha} A_{\alpha}$$

which implies

$$A^c = \bigcup_{\alpha} A_{\alpha}^c$$

also notice that  $A$  implies  $A^c \subseteq X \setminus A$

Now let  $x \in X \setminus A$  be some arbitrary point

we now get from the preceeding lines

$$x \in \bigcup_{\alpha} A_{\alpha}^c$$

so there exists at least one  $A_{\alpha}$  that is closed and  $x \in A_{\alpha}^c$

Since  $A_{\alpha}^c$  is open and  $x \in A_{\alpha}^c$  this means that  $x \in (A_{\alpha}^c)$

And given that  $A^c \subseteq X \setminus A$ , we are done with this direction.

( $\Leftarrow$ )

So suppose now that

$$\forall U \in \mathcal{T} : A \cap U \subseteq X \setminus A$$

This defines a collection  $\{U_{\alpha}\}_{\alpha \in X \setminus A}$  where we pick one neighbourhood per  $x \in X \setminus A$ , satisfying the preceeding statement

Its hard to escape the noticing that

$$A^c = X \setminus A = \bigcup_{x \in X \setminus A} \{x\} \subseteq \bigcup_{x \in X \setminus A} U_{\alpha} \subseteq X \setminus A = A^c$$

where the first inclusion is given by the fact that there exists such a neighbourhood for each point in  $X$

we conclude by recalling that the intersection of arbitrary closed sets, is closed which happens to be  $(A^c)^c = A$

## lemma 3

Let  $A$  be some subset of some topological space  $X$

$$x \in A \text{ iff } \forall U \in \mathcal{T} : x \in U \Rightarrow A \cap U \neq \emptyset$$

### Proof

( $\Rightarrow$ )

Suppose  $x \in A$ , so by definiton of the closure for any closed set  $C$  with  $x \in C$  we have

$$x \in C$$

Now suppose towards absurdity that

$$x \in (A^c) : A \cap U = \emptyset$$

This implies  $A \subseteq A^c$ , since  $A^c$  is open,  $A$  is closed and it contains  $x$  so we have

$$x \in A^c \text{ but this is absurd since } x \in A \text{ which would imply that } A \subseteq A^c$$

So there cannot exist such  $x$  which proofs that

$$\forall x \in (A^c) : x \notin A$$

( $\Leftarrow$ )

Now we consider any point  $x \in X$  that satisfies

$$\forall U \in \mathcal{B} : x \in U$$

Now assume towards absurdity that there exists a closed set  $C$  with  $x \in C$  and

This implies that  $x \in U^c$  which is open and thus  $x \in U^c$

So we have  $x \in U^c$ , but this cannot be true because

$$x \in U \text{ implies } x \in U^c \text{ so } U \cap U^c \neq \emptyset$$

this is absurd, so such a  $C$  cannot exist, which means  $x$  is a member of every such  $U$  so

$$\forall U \in \mathcal{B} : x \in U \text{ which implies}$$

$$x \in \bigcap_{U \in \mathcal{B}} U \text{ and we are done}$$

## Def. Filter

A collection  $\mathcal{F}$  of subsets of  $X$  is called a filter iff

1.  $X \in \mathcal{F}$
2. if  $A \in \mathcal{F}$  and  $A \subseteq B \subseteq X$  then  $B \in \mathcal{F}$
3. if  $A \in \mathcal{F}$  then  $A^c \notin \mathcal{F}$

A filter  $\mathcal{F}$  is said to be proper iff

## Theorem 4, bradley

Let  $\mathcal{B}$  be a subset of some topological space  $X$  then

$$\mathcal{F} = \{A \subseteq X : \exists \mathcal{B}' \subseteq \mathcal{B} \text{ s.t. } \bigcap \mathcal{B}' \subseteq A\}$$

## Proof

( $\Rightarrow$ )

suppose  $A \in \mathcal{F}$

Define the filter base  $\mathcal{B}' := \{B \subseteq A : B \in \mathcal{B}\}$

and the filter  $\mathcal{F}' = \{C \subseteq X : \exists B \in \mathcal{B}' \text{ s.t. } B \subseteq C\}$

Because  $A \subseteq X$  and  $A \in \mathcal{F}$  we have  $X \in \mathcal{F}'$  satisfying the first property of a filter

Now suppose that  $C \in \mathcal{F}'$  then any superset  $D$  that is also a subset of  $X$ , is in the filter because

$$(C \subseteq D) \Rightarrow C \in \mathcal{F}' \text{ and therefore we have}$$

$$C \subseteq D \subseteq X \text{ which implies } D \in \mathcal{F}'$$

which proves the second property of a filter

Lastly, consider  $C \in \mathcal{F}'$  we aim to show  $C^c \notin \mathcal{F}'$

Its clear that  $C \in \mathcal{B}'$  with

$$C \subseteq A \text{ and}$$

$$C \subseteq X \text{ which gives}$$

$$C \subseteq A \text{ and } C \subseteq X \Rightarrow C \subseteq A \cap X = A$$

where  $C \in \mathcal{B}'$  because finite intersections of opens is open and both contain  $C$  by def.

so therefore  $C \in \mathcal{F}'$

which means that  $C \in \mathcal{F}'$

which proves that  $\mathcal{F}'$  is indeed a filter

Now recall from lemma 3 that because  $C \in \mathcal{F}'$  we have

$$\forall U \in \mathcal{B} : C \subseteq U$$

So for any superset  $D \supseteq A$  we conclude

$$C \subseteq A \subseteq D \text{ which shows that the filter is proper}$$

Lastly, because of  $A \subseteq X$  we have  $A \in \mathcal{F}'$  but also

$\forall \in () : A \subseteq$  which implies

$() \subseteq$  which shows that the filter 'converges' to

this concludes this direction of the proof

( $\Leftarrow$ )

Let  $\in X$  be some point and let be a proper filter satisfying the assumptions, that is

$() \subseteq$  and  $A \in$

by the third property of any filter we have for any  $\in ()$

$A \in$

since the filter is proper  $A$

by lemma 3 we get  $\in A$  which concludes this proof
